

Download Types-of-laser-treatment

Acne scarring can sometimes develop as a complication of acne. Any type of acne spot can lead to scarring, but it's more common when the most serious types of spots (nodules and cysts) burst and damage nearby skin. Pregnancy-associated striae are the result of the rapid stretching of the mother's skin and an increased level of a hormone called cortisol. Cortisol is produced in the adrenal glands and increased levels of the hormone help the pregnant woman deal with the stresses of pregnancy. Vitiligo is a skin disorder that does not produce any harmful or painful effects. The only problem it brings is a very noticeable skin color change. A more invasive option for lightening dark spots is laser treatment. It works by targeting dark spots with concentrated light energy, and removes the skin layer by layer.
